Abstract

We give an elementary proof of a generalization of the Seidel-Kaneko and Chen-Sun formula involving the Bernoulli numbers.

Keywords: Bernoulli numbers, Bernoulli polynomials, Integer sequences.

MSC: 11B68, 11B83

1. Introduction

The Bernoulli Numbers B_n , $n = 0, 1, 2, \dots$ are defined by the exponential generating function:

$$B(z) = \frac{z}{e^z - 1} = \sum_{n=0}^{\infty} B_n \frac{z^n}{n!}. \quad (1.1)$$

As (1.1) implies that $B(-z) = z + B(z)$, we have:

$$(-1)^n B_n = B_n + \delta_1^n, \text{ for } n \geq 0. \quad (1.2)$$

where the notation δ_i^n is the classical Kronecker symbol which equals 1 if $n = i$ and 0 otherwise. Consequently, we have $B_1 = -\frac{1}{2}$, and $B_n = 0$, when n is odd and $n \geq 3$. Let us define $\epsilon_n := \frac{1 + (-1)^n}{2}$, thus:

$$\epsilon_n B_n = B_n + \frac{1}{2} \delta_1^n, \text{ for } n \geq 0. \quad (1.3)$$

Note that the Bernoulli polynomials can be defined by the following function:

$$B(x, z) := \frac{ze^{xz}}{e^z - 1} = \sum_{n=0}^{\infty} B_n(x) \frac{z^n}{n!}.$$

Thus, we have:

$$\sum_{n=0}^{\infty} B_n(x) \frac{z^n}{n!} = \left(\sum_{n=0}^{\infty} B_n \frac{z^n}{n!} \right) \left(\sum_{n=0}^{\infty} x^n \frac{z^n}{n!} \right).$$

Therefore the polynomial $B_n(x)$ satisfies the following equality:

$$B_n(x) = \sum_{k=0}^n \binom{n}{k} x^{n-k} B_k. \quad (1.4)$$

We note also that:

$$B(x+1, z) - B(x, z) = \sum_{n=0}^{\infty} (B_n(x+1) - B_n(x)) \frac{z^n}{n!} = ze^{xz}.$$

Consequently, we deduce the following property of $B_n(x)$:

$$B_n(x+1) - B_n(x) = nx^{n-1}, \text{ for } n \geq 1. \quad (1.5)$$

In this paper, we are extending the well-known following formulae involving Bernoulli Numbers. First, the Seidel formula (1877) [4], re-discovered later by Kaneko [3] (1995):

$$\sum_{k=0}^n \binom{n+1}{k} (n+k+1) B_{n+k} = 0, \text{ for } n \geq 1.$$

And secondly, the Chen-Sun formula [1] (2009):

$$\sum_{k=0}^{n+3} \binom{n+3}{k} (n+k+3)(n+k+2)(n+k+1) B_{n+k} = 0. \quad (1.6)$$

Our main result consists on the following:

Theorem 1.1. *For given odd natural q and for natural number $n \geq 0$, we have the equality:*

$$\sum_{k=0}^{n+q} \binom{n+q}{k} (n+k+q)(n+k+q-1) \cdots (n+k+1) B_{n+k} = 0. \quad (1.7)$$

Obviously, this result gives the Seidel-Kaneko formula when $q = 1$, and the Chen-Sun formula when $q = 3$.

2. Proof of the main result

For a given odd number q and for an integer number $n \geq 0$, we consider the polynomials:

$$H(x) = \frac{1}{2}x^{n+q}(x-1)^{n+q},$$

and

$$K(x) = \sum_{k=0}^{n+q} \frac{\epsilon_{n+k}}{(n+q+k+1)} \binom{n+q}{k} (B_{n+q+k+1}(x) - B_{n+q+k+1}). \quad (2.1)$$

By the binomial theorem, we deduce:

$$H(x) = \frac{1}{2} \sum_{k=0}^{n+q} (-1)^{n+k+1} \binom{n+q}{k} x^{n+q+k}, \quad (2.2)$$

and

$$H(x+1) = \frac{1}{2} \sum_{k=0}^{n+q} \binom{n+q}{k} x^{n+q+k}. \quad (2.3)$$

Thus, by using the equality property (1.5), we verify that:

$$K(x+1) - K(x) = H(x+1) - H(x) = \sum_{k=0}^{n+q} \epsilon_{n+k} \binom{n+q}{k} x^{n+q+k}. \quad (2.4)$$

Moreover

$$K(0) = H(0) = 0. \quad (2.5)$$

Then, (2.2), (2.3), (2.4) and (2.5) imply:

$$K(x) = H(x).$$

If $[x^n]P(x)$ denotes the coefficient of x^n in the polynomial $P(x)$, we can write:

$$[x^{q+1}]K(x) = [x^{q+1}]H(x). \quad (2.6)$$

So, from (1.4)

$$[x^{q+1}]K(x) = \sum_{k=0}^n \frac{\epsilon_{n+k} B_{n+k}}{(n+q+k+1)} \binom{n+q}{k} \binom{n+q+k+1}{q+1}, \quad (2.7)$$

and from (2.2), we have:

$$[x^{q+1}]H(x) = \frac{1}{2} \binom{n+q}{1-n}. \quad (2.8)$$

From (1.3), we know that:

$$\epsilon_{n+k}B_{n+k} = B_{n+k} + \frac{1}{2}\delta_{1-n}^k. \quad (2.9)$$

Since

$$\begin{aligned} \sum_{k=0}^{n+q} \frac{\delta_{1-n}^k}{2(n+q+k+1)} \binom{n+q}{k} \binom{n+q+k+1}{q+1} &= \frac{1}{2(q+1)} \binom{n+q}{1-n} \binom{q+1}{q} \\ &= \frac{1}{2} \binom{n+q}{1-n}. \end{aligned} \quad (2.10)$$

We deduce, from (2.7), (2.9) and (2.10) that:

$$[x^{q+1}]K(x) = \sum_{k=0}^{n+q} \frac{B_{n+k}}{(n+q+k+1)} \binom{n+q}{k} \binom{n+q+k+1}{q+1} + \frac{1}{2} \binom{n+q}{1-n}. \quad (2.11)$$

It follows from (2.6), (2.8) and (2.11) that:

$$\sum_{k=0}^{n+q} \frac{1}{(n+q+k+1)} \binom{n+q}{k} \binom{n+q+k+1}{q+1} B_{n+k} = 0, \quad (2.12)$$

and by multiplying by $(q+1)!$, we obtain, finally, the aimed result which is:

$$\sum_{k=0}^{n+q} \binom{n+q}{k} (n+k+q)(n+k+q-1) \dots (n+k+1) B_{n+k} = 0.$$

This ends our proof.
